## Abstract

We propose to make a high precision measurement of the two-photon exchange contribution (TPE) in elastic electron-neutron scattering at a four-momentum transfer  $Q^2 = 4.5$   $(\text{GeV}/c)^2$ . While significant efforts to study the two-photon-exchange have focused around elastic electron-proton scattering, the impact of TPE on neutron form factors was never examined experimentally. The proposed experiment will provide the very first assessment of the two-photon exchange in electron-neutron scattering, which will be important for understanding the nucleon form factor physics.

The proposed experiment will be performed in Hall A using the BigBite (BB) spectrometer to detect the scattered electrons and the Super-BigBite (SBS) to detect the protons and neutrons. The experiment should run concurrently with the E12-09-019  $G_M^n$  and E12-17-004  $G_E^n$ -Recoil experiments, which are expected to run in 2021. The experimental setup of the proposed experiment will be identical to that of E12-09-019 experiment.

The “ratio” method will be used to extract the electric form factor of the neutron  $G_E^n$  by scattering unpolarized electrons from deuterium quasi-elastically at two beam energies 4.4 and 6.6 GeV and electron scattering angles 41.9 and 23.3 degrees respectively. In the proposed approach, systematic errors are greatly reduced compared to those in the traditional single electron arm configuration. Several experiments at Mainz and JLab have used the ratio method to measure the neutron magnetic form factor in the past years. The method can be extended to extract the neutron electric form factor even with less stringent requirements on the knowledge of the absolute neutron detection efficiency and experimental kinematics.

## I. INTRODUCTION

In 1950's, a series of experiments performed by R. Hofstadter [1] revealed that the nucleons have a substructure (would be called later the quarks and gluons). The experiment confirmed M. Rosenbluth's theory [2] based on one-photon exchange approximation. In the Born approximation, where the interaction between the electron and the nucleon occurs *via* an exchange of a one virtual photon (OPE), the unpolarized  $e - N$  elastic cross section can be expressed in terms of a nucleon magnetic,  $G_M$ , and electric,  $G_E$ , form factors. These form factors describe the deviation from a point-like scattering cross section:

$$\left( \frac{d\sigma}{d\Omega} \right)_{eN \rightarrow eN} = \frac{\sigma_{Mott}}{\epsilon(1 + \tau)} [\tau \cdot G_M^2(Q^2) + \epsilon \cdot G_E^2(Q^2)] = \sigma_T + \epsilon \cdot \sigma_L, \quad (1)$$

where  $E$  and  $E'$  are the incident and scattered electron energies, respectively,  $\theta$  is the electron scattering angle,  $\tau \equiv -q^2/4M^2$ , with  $-q^2 \equiv Q^2 = 4EE' \sin(\theta/2)$  being the negative four momentum transfer square,  $M$  is the nucleon mass, and  $\epsilon = [1 + 2(1 + \tau) \tan^2(\theta/2)]^{-1}$  is the longitudinal polarization of the virtual photon,  $\sigma_L$  and  $\sigma_T$  are the cross sections for longitudinally and transversely polarized virtual photons, respectively.

The linear  $\epsilon$  dependence of the cross section is due to  $\sigma_L$  term, see Eq. 1. The ratio  $\sigma_L/\sigma_T$  is a Rosenbluth slope related to  $G_E/G_M$  (in OPE), see Fig. 1. The data show that at  $Q^2$  of 4-5  $(\text{GeV}/c)^2$  the Rosenbluth slope is three-four times larger than it suppose to be (in OPE) for the observed values of the  $G_E^p/G_M^p$  ratio.

The nucleon electromagnetic form factors can reveal a lot of information about the nucleon internal structure, as well as the quark distribution. The form factors depend only on one variable the negative square of the four-momentum transfer carried by the photon,  $Q^2$ . In the limit of large  $Q^2$ , pQCD provides well-motivated predictions for the  $Q^2$ -dependance of the form factors and their ratio. However, it was never predicted at what  $Q^2$  range the pQCD prediction (scaling) will be valid. Studies of GPDs show that pQCD validity will require a very large  $Q^2$  of 100  $(\text{GeV}/c)^2$ . It was discovered at JLab, using the double polarization methods, that the proton electric and magnetic form factors behave differently starting at

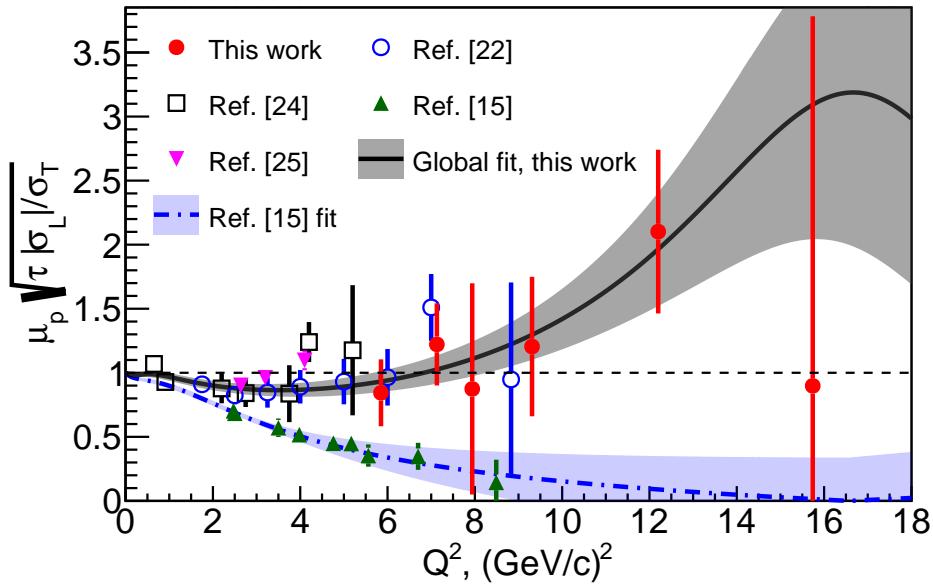

FIG. 1. The square root of Rosenbluth slope, corrected for kinematical factor  $\sqrt{\tau}$  and  $\mu_p$ , observed in elastic electron-proton scattering, adopted from Ref. [3].

<sup>27</sup>  $Q^2 \approx 1 \text{ (GeV/c)}^2$ .

<sup>28</sup> Experimentally, the nucleon form factors can be measured using one of two techniques:  
<sup>29</sup> polarization transfer technique and Rosenbluth technique. The polarization method exam-  
<sup>30</sup> ines the polarization transfer from longitudinally polarized electron to the recoiling nucleon  
<sup>31</sup> and determine the resulting azimuthal asymmetry distribution using a polarimeter. Alter-  
<sup>32</sup> natively, one can use the polarized electron beam and a polarized target. While in the  
<sup>33</sup> Rosenbluth method, the electric and magnetic form factors can be separated by making  
<sup>34</sup> two or more measurements with different  $\epsilon$  values (*i.e.* different beam energies and angles),  
<sup>35</sup> but with same  $Q^2$  value. Rosenbluth technique requires an accurate measurement of the  
<sup>36</sup> cross section and suffers from large systematic uncertainties arising from several factors. For  
<sup>37</sup> instance, an accurate knowledge of the neutron detector efficiency is required.

<sup>38</sup> When comparing the values of  $G_E^p/G_M^p$  obtained from both techniques, a significant dis-  
<sup>39</sup> crepancy was observed (see Fig. 1). Such discrepancy implies a potential problem in our  
<sup>40</sup> understanding of the nucleon substructure. Many efforts were made in order to provide  
<sup>41</sup> legitimate explanation, and it is believed that the inconsistency is due to contribution of

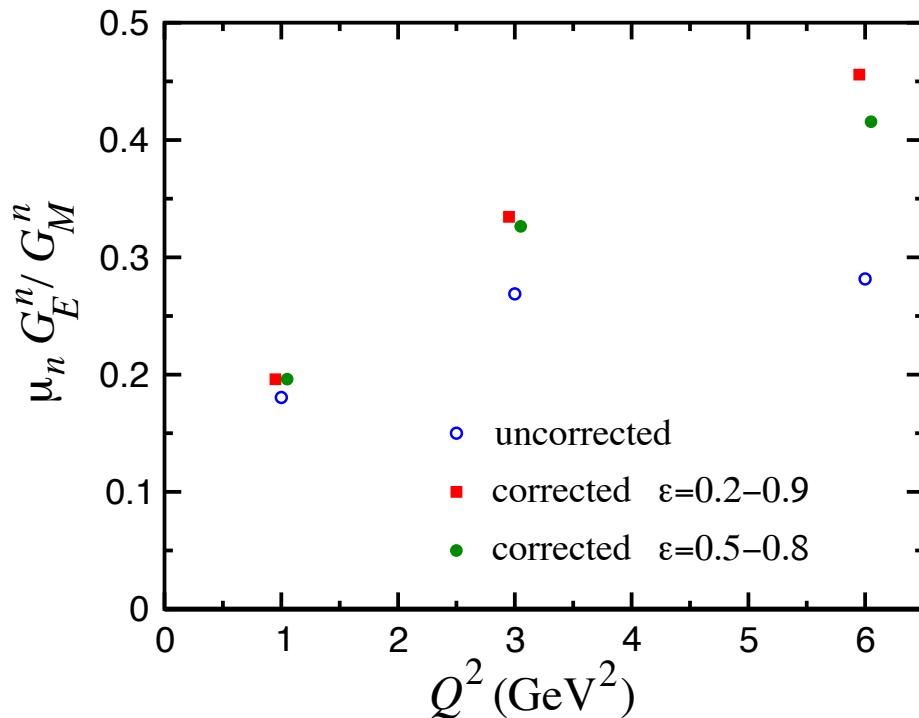

FIG. 2. Projected impact of TPE on  $G_E^n/G_M^n$  using LT separation, according to Ref. [4].

42 two-photon exchange in  $e - N$  elastic scattering process, see Refs. [5, 6]. Predictions made  
 43 for the neutron case are shown in Fig. 2 , adopted from [4]. The contribution of TPE could  
 44 reach about 30% of Rosenbluth slope value at 5 (GeV/c) $^2$ .

45 In the following we propose to make precision L/T separation of the elastic electron-  
 46 neutron cross section and first experimental assessment of the two-photon exchange contri-  
 47 bution on the neutron magnetic form factor measurements (see also Ref. [7]). The result of  
 48 the nTPE experiment will likely add a new component to our understanding of the elastic  
 49 electron-nucleon process.

50

## II. PHYSICS MOTIVATION

51      The nucleon plays the same central role in hadronic physics that the hydrogen atom does  
 52      in atomic physics and the deuteron in the physics of nuclei. The structure of the nucleon  
 53      and its specific properties, such as charge, magnetic moment, size, mass; the elastic electron  
 54      scattering form factors, resonances; and structure functions in DIS, are of fundamental sci-  
 55      entific interest. The isospin is a fundamental property of the nucleon, so both the proton and  
 56      neutron investigations are important to do. By using data on the proton and neutron form  
 57      factors the flavour structure could be explored [8]. It is already provided the most direct  
 58      evidence for a diquark correlation in the nucleon [9–11].

59      Hadron structure, as seen in elastic electron scattering, in one-photon approximation,  
 60      defined by two functions of four momentum transfer square. They are: the helicity conserving  
 61      Dirac form factor,  $F_1$ , which describes the distribution of the electric charge, and the helicity  
 62      non-conserving Pauli form factor,  $F_2$ , describes the distribution of the magnetic moment.  
 63      These two form factors are the ingredients of the hadronic current. These form factors  
 64      contain information on the transverse charge distribution for an unpolarized and transversely  
 65      polarized nucleon, respectively, in the infinite momentum frame [12, 13].

66      The Sachs form factors,  $G_E$  and  $G_M$ , the ratio of which will be extracted directly from  
 67      the data, are related to  $F_1$  and  $F_2$  by

$$F_1 = \frac{G_E + \tau G_M}{1 + \tau} \text{ and } F_2 = \frac{G_M - G_E}{\kappa(1 + \tau)}, \quad (2)$$

68      where  $\kappa$  is the nucleon anomalous magnetic moment.

69      Already twenty four years ago, important developments in QCD phenomenology has  
 70      been the exploration of the generalized parton distribution (GPD) formalism [14–16], which  
 71      provides relations between inclusive and exclusive observables. The nucleon elastic form  
 72      factors  $F_1$  and  $F_2$  are given by the first moments of the GPDs

$$F_1(t) = \sum_q \int_0^1 H^q(x, \xi, t, \mu) dx \text{ and } F_2(t) = \sum_q \int_0^1 E^q(x, \xi, t, \mu) dx, \quad (3)$$

73      where  $H^q$  and  $E^q$  are two of the generalized parton distributions,  $x$  is the standard Bjorken  
 74       $x$ ,  $\xi$  is the “skewness” of the reaction,  $t$  is the four-momentum transferred by the electron,

<sup>75</sup>  $\mu$  is a scale parameter necessary from the evolution over  $Q^2$ , analogous to DIS parton distributions, and the sum is over all quarks and anti-quarks. These may be accessed through processes such as deeply virtual Compton scattering, where the interaction is factorized into a hard part with the virtual photon/photon interactions with an individual quark and a soft part of the residual system where the GPD information is contained.

<sup>80</sup> Fundamental nucleon feature, the spin, is related to GPDs, as shown by X. Ji [15]. The moments of GPDs can yield information, according to the Ji's Angular Momentum Sum Rule, on the contribution to the nucleon spin from quarks and gluons, including both the quark spin and orbital angular momentum.

<sup>84</sup> At present, experimental measurements of GPDs are still scarce. Until high  $Q^2$  DVCS data becomes available, work has been done to attempt to parameterize these GPDs, which rely heavily on data from electromagnetic form factors and parton distributions from DIS as constraints [17]. Data at high  $Q^2$  for  $G_E^n$  would contribute significantly in the development of these models.

<sup>89</sup> As we presented above the form factors are important components for GPDs development. However, the cross section of elastic  $e-p$  scattering contains a significant contribution to  $\sigma_L$ , which at high  $Q^2$  is much larger than theory calculations expected [18]. Such an alarming observation underlines that understanding of TPE effect is essential for hadron physics.

93

### III. TECHNIQUE

94 This proposal is based on instrumentation, simulation, and analysis development made  
 95 by the GMn/SBS collaboration for the GMn, E12-09-019, experiment [? ]. The GMn  
 96 experiment is one of several form factor experiments approved by JLab PAC. The SBS  
 97 spectrometer was funded by DOE with large contributions provided by the collaborating  
 98 institutions from USA, Italy, UK, and Canada. The apparatus and DAQ installation will  
 99 start in 2020 and the data taking run is expected to be in summer-fall 2021.

100 The neutron form factors are challenging to be determine experimentally especially be-  
 101 cause there is no free neutron target. However, since the deuterium is a loosely coupled  
 102 system, it can be viewed as the sum of a proton target and a neutron target. In fact, quasi-  
 103 elastic scattering from deuterium has been used to extract the neutron magnetic form factor,  
 104  $G_M^n$ , at modestly high  $Q^2$  for decades [19, 20] in the single arm ( $e,e'$ ) experiments. How-  
 105 ever, the proton cross section needs to be subtracted by applying a single-arm quasi-elastic  
 106 electron-proton scattering. This “proton-subtraction” technique suffers from a number sys-  
 107 tematic uncertainties e.g. contributions from inelastic and secondary scattering processes.

108 Many year ago, L. Durand [21] proposed the so-called “ratio-method” based on the mea-  
 109 surement of both  $D(e,e'n)$  and  $D(e,e'p)$  reactions. In this method, many of the systematic  
 110 errors are cancel out. Several experiments [22–24] have applied the ratio-method to deter-  
 111 mine the neutron magnetic form factor.

112 The GMn/SBS experiment [? ] will take data for elastic  $e - n$  scattering for several  
 113 kinematics with  $Q^2$  from 3.5 up to 13.5  $(\text{GeV}/c)^2$ . We propose to use this method to  
 114 measure Rosenbluth slope and extract (in OPE approximation) the neutron electric form  
 115 factor,  $G_E^n$ , at one value of momentum transfer. In fact, one of required data points will  
 116 be taken by the GMn experiment, so an additional measurement is needed only for one  
 117 kinematics.

118 Data will be collected for quasi-elastic electron scattering from deuteron in process  
 119  $D(e, e'n)p$ . A complementary  $D(e, e'p)n$  data will be taken to calibrate the experiment ap-  
 120 paratus. The current knowledge of the  $e - p$  elastic scattering cross section (obtained in the  
 121 single arm  $H(e,e')p$  and  $H(e,p)e'$  experiments) will be also used for precision determination

<sup>122</sup> the experiment kinematics.

<sup>123</sup> Applying Rosenbluth technique to measure  $G_E^n$  requires accurate measurement of the cross  
<sup>124</sup> section and suffers from large uncertainties. To overcome this issue, we propose to extract  
<sup>125</sup> the value of  $G_E^n$  from the ratio of quasi-elastic yields,  $R_{n/p}$ , in scattering from a deuteron  
<sup>126</sup> target as follows:

$$R_{n/p} \equiv R_{observed} = \frac{N_{e,e'n}}{N_{e,e'p}} \quad (4)$$

<sup>127</sup>  $R_{observed}$  needs to be corrected to extract the ratio of e-n/e-p scattering from nucleons:

$$R_{corrected} = f_{corr} \times R_{observed} , \quad (5)$$

<sup>128</sup> where the correction factor  $f_{correction}$  takes into account the variation in the hadron efficiencies  
<sup>129</sup> due to changes of  $e - N$  Jacobian, the radiative corrections, and absorption in path from the  
<sup>130</sup> target to the detector, and small re-scattering correction.

<sup>131</sup> In one-photon approximation,  $R_{corrected}$  can be presented as:

$$R_{corrected} = \frac{\sigma_{Mott}^n \cdot (1 + \tau_p)}{\sigma_{Mott}^p \cdot (1 + \tau_n)} \times \frac{\epsilon \sigma_L^n + \sigma_T^n}{\epsilon \sigma_L^p + \sigma_T^p} \quad (6)$$

It is important that the ratio  $R_{Mott} = \frac{\sigma_{Mott}^n \cdot (1 + \tau_p)}{\sigma_{Mott}^p \cdot (1 + \tau_n)}$  could be determine with very high relative accuracy even with modest precision for the beam energy, electron scattering angle, and detector solid angle. Now, let us write the  $R_{corrected}$  at two values of  $\epsilon$  using  $R_c^{n(p)} = \sigma_L^{n(p)} / \sigma_T^{n(p)}$  as:

$$R_{corrected,\epsilon_1} = R_{Mott,\epsilon_1} \times \frac{\epsilon_1 \sigma_L^n + \sigma_T^n}{\epsilon_1 \sigma_L^p + \sigma_T^p} \quad R_{corrected,\epsilon_2} = R_{Mott,\epsilon_2} \times \frac{\epsilon_2 \sigma_L^n + \sigma_T^n}{\epsilon_2 \sigma_L^p + \sigma_T^p}$$

In these two equations there are two unknown variables:  $\sigma_L^n$  and  $\sigma_T^n$ . The dominant contribution to the uncertainty of the slope of the cross section vs.  $\epsilon$ ,  $S_c^n = \sigma_L^n / \sigma_T^n$ , will come from the uncertainty of  $S_c^p$ . At  $Q^2=4.5$  (GeV/c)<sup>2</sup>, according to the global analysis of  $e - p$  cross section [3], the value of  $S_c^p$  is close to  $1/(\tau \mu_p^2) = 0.107$  with uncertainty of 0.01. The resulting equation for  $S_c^n$  is:

$$A = B \times \frac{1 + \epsilon_1 S_c^n}{1 + \epsilon_2 S_c^n} \approx B \times (1 + \Delta \epsilon \cdot S_c^n),$$

132 where the variable  $A = R_{corrected,\epsilon_1}/R_{corrected,\epsilon_2}$  will be measured with relative precision of  
 133 0.1%. Assuming, for this estimate, equal values of  $Q^2$  for two kinematics, the  $\tau$  and  $\sigma_T$  for  
 134 two kinematics are canceled out, and the variable  $B = R_{M,\epsilon_1}/R_{M,\epsilon_2} \times (1 + \epsilon_2 S_c^p)/(1 + \epsilon_1 S_c^p)$ .  
 135 For actual small range of  $\epsilon$  and small value of the slope, the  $B \approx (1 - \Delta\epsilon \cdot S_c^p)$ . The value  
 136 of  $B$  will be determined from global proton  $e - p$  data to a precision of  $0.25 \times 0.01$ .

137 At  $Q^2=4.5$  ( $\text{GeV}/c$ ) $^2$  the ratio  $\mu_n G_E^n/G_M^n$  is of  $0.55 \pm 0.05$ , see the review [25]. In a  
 138 simplest model, the slope  $S_c^n$  is a sum of the slope due to  $G_E^n/G_M^n$  and the TPE contribution.  
 139 If we use for TPE the prediction [4], shown in Fig. 2, the TPE leads to increase of  $S_c^n$  by a  
 140 factor of 2, so the result of this experiment for TPE will be  $0.069 \pm 0.012 \pm 0.01$ , where the  
 141 first uncertainty is due to accuracy of  $G_E^n/G_M^n$  and the second one due to projected precision  
 142 of this experiment. It would be a 4-4.5 sigma observation of the neutron TPE.

143

#### IV. EXPERIMENTAL SETUP

144 As illustrated in Fig. 3, this experiment will study electron scattering from a 15 cm  
 145 long liquid Deuterium target held in a vacuum. The scattered electron will be detected  
 146 in the BigBite spectrometer with an upgraded electron detector stack. The neutron arm is  
 147 arranged with a dipole magnet 48D48 (SBS) and a segmented hadron calorimeter HCAL. The  
 148 whole detector package was designed and is now under assembling for the GMn, E12-09-019,  
 149 experiment.

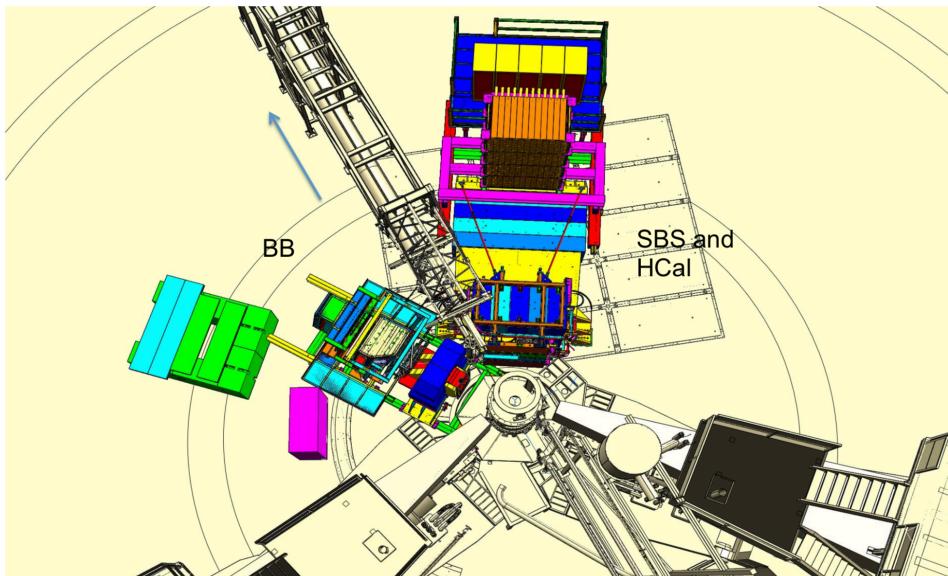

FIG. 3. Layout of the experimental setup in nTPE.

150

##### 1. Parameters of the SBS

151 The 48D48 magnet from Brookhaven was acquired as part of the Super Bigbite project  
 152 and will be available for this experiment. It consists of a large dipole magnet which provides  
 153 a field integral of about  $1.7 \text{ T} \cdot \text{m}$ , allowing for quasielastic protons to be sufficiently deflected  
 154 to allow clear differentiation from neutrons. The active field volume has an opening of  $46 \times$   
 155  $25 \text{ vertical} \times \text{horizontal}$ ), matching the aspect ratio of the neutron arm, and a depth of 48  
 156 cm.

157     The placement of this magnet will be 1.6 m away from the target, which would normally  
158    interfere with the beamline. To accommodate this, modifications were made to the iron yoke  
159    such that the beamline will pass through the magnet yoke area.

160     The field configuration will be such that positively charged particles will be deflected  
161    upwards away from the hall floor. For a field integral of 1.7 Tesla-m, protons of momentum  
162    2.5 GeV/c will be deflected 250 mrad, which translates to a displacement of xxm. Including  
163    expected detector resolution, the  $p_{miss,\perp}$  distribution will be similar to what was seen in  
164    E02-013, so cuts of < 100 MeV/c will be appropriate. Monte Carlo simulations show a  
165    contamination of charged quasielastics to be negligible.

166     The presence of the magnet also works to sweep low energy charged particles from the  
167    target away from the neutron arm. Particles of momentum less than 1.3 GeV/c will be  
168    entirely swept outside of the neutron arm acceptance. This greatly reduces the amount of  
169    charged low energy background.

170

### A. The BigBite Spectrometer

171 Scattered electrons will be detected in the BigBite spectrometer. The spectrometer con-  
 172 sists of a single dipole magnet (with magnetic field approximately 1.2 T) and a detection  
 173 system, see Fig. 4.

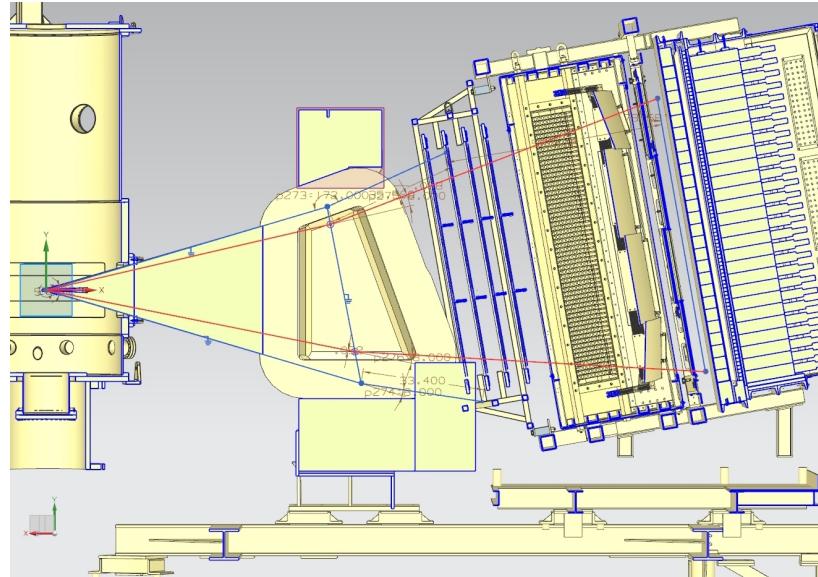

FIG. 4. The BigBite spectrometer with the upgraded detector stack.

174

#### 1. GEM Chambers

175 To perform the tracking of charged particles under the high rates anticipated for this  
 176 experiment, the drift chambers were replaced with gas electron multiplier (GEM) detectors.  
 177 These detectors have proven to be capable of operating under luminosities of  $25 \text{ kHz/mm}^2$   
 178 for the COMPASS experiment at CERN and the spatial resolution of each of these chambers  
 179 is anticipated to be about  $70 \mu\text{m}$ . There will be two sets of GEMs placed on each side of the  
 180 GRINCH Cherenkov detector.

181 The set of GEMs in front of the GRINCH is composed of four layers of GEMs. Two of  
 182 these layers have been built by will the SBS collaborators from INFN. They are composed

183 three modules each, measuring  $40 \times 50 \text{ cm}^2$ , such that each layer covers  $40 \times 150 \text{ cm}^2$  (the  
 184 long dimension being vertical, along the dispersive direction). The readout of these modules  
 185 are oriented in the  $x/y$  direction *i.e.* parallel and perpendicular to the dispersive direction  
 186 (horizontal and vertical). The two other layers are being built by the SBS collaborators from  
 187 UVA. They are composed of a single module measuring  $40 \times 150 \text{ cm}^2$ , the long dimension  
 188 again being vertical and along the dispersive direction. The readout of these modules are  
 189 oriented in the  $u/v$  direction *i.e.*  $\pm 30$  degrees with respect to the horizontal direction.

190 The set of GEMs behind the GRINCH has been built by the SBS collaborators from  
 191 UVA. It is composed of a single layer composed of four modules measuring  $50 \times 60 \text{ cm}^2$ ,  
 192 such that the layer covers  $60 \times 200 \text{ cm}^2$  (the long dimension again being along the dispersive  
 193 direction). The readout of these modules are all oriented in the  $x/y$  direction.

194 The level background in the GEMs have been evaluated, thanks to G4SBS ([? ] abd  
 195 Sec. V) for the  $G_M^n$  experimental readiness review. For the  $G_M^n$  highest  $Q^2$  point (which is the  
 196 most constraining, since it combines mandatory maximum luminosity and smaller BigBite  
 197 angles, the background level in the front GEMs are of the order of  $120 \text{ kHz/cm}^2$  for the front  
 198 GEM layers, and below  $50 \text{ kHz/cm}^2$  for the back GEM. To perform the GEM tracking within  
 199 such a background environment, we use the cluster reconstructed in the BigBite shower as  
 200 a track seed to clean the large combinatorics that would otherwise be created by the large  
 201 number of hits. After this, the main challenge is the separation by the clustering algorithm  
 202 of the signal and background hits to minimize track smearing. At this level of background, a  
 203 TreeSearch tracking algorithm combined with a fairly simple cluster separation algorithm has  
 204 already proven to achieve 70% efficiency at nominal luminosity. A better cluster separation  
 205 algorithm is currently being developed and should allow to significantly improve this figure.

206

## 2. Shower/Preshower

207 The electromagnetic calorimeter configuration consists of two planes of lead glass blocks  
 208 which we call the preshower and shower. The preshower, located about 80 cm behind  
 209 the first GEM chamber, consists of a  $2 \times 26$  plane of  $37 \text{ cm} \times 9 \text{ cm}$  blocks. The shower, about  
 210 1 m behind the first GEM chamber, consists of an  $7 \times 27$  array of  $8.5 \text{ cm} \times 8.5 \text{ cm}$  blocks.

211 Sums over these blocks form the physics event trigger for the experiment.

212 The preshower signal can be used to provide an additional method of pion rejection.  
213 By selecting low preshower signals, a pion rejection factor of 1:50 can be achieved through  
214 optimization. Despite higher particle rates, pion rejection performance is anticipated to  
215 be similar to that achieved for Transversity, E06-010. By measuring the pedestal widths  
216 and resolution for E06-010 and scaling to this proposal's conditions, overall relative energy  
217 resolution for the detector is expected to become worse by a factor of 1.6, to about  $\sigma_{\delta E/E} =$   
218 25%.

219 *3. Timing hodoscope*

220 The BigBite timing hodoscope has been built the the SBS collaborators from Glasgow,  
221 to replace the BigBite scintillator plane. It will be composed of 90 bars stacked in a plane,  
222 each with dimensions 1 in.  $\times$  1 in.  $\times$  60 cm. The paddle stack will be oriented such as  
223 the long dimension of the bars is horizontal *i.e.* perpendicular to the dispersive direction.  
224 Each of these elements are readout by a PMT on each side, mostly to provide measurement  
225 redundancy.

226 This plane will primarily be used to provide a signal for nucleon time of flight reconstruc-  
227 tion. A time resolution of 200 ps is anticipated. This fine segmentation is meant to lower the  
228 rates in the detector. Background studies made for the  $G_M^n$  experimental readiness review [?]  
229] demonstrated that the rates experienced by each element was  $\leq$  500 kHz at a luminosity  
230 of  $2.8 \times 10^{38}$  cm $^{-2}$  s $^{-2}$ . The PMTs pulses are processed by NINO front-end cards which,  
231 when the PMT pulse crosses the NINO threshold, will produce a digital signal to be readout  
232 by CAEN 1190 TDCs which record a leading time and a trailing time.

233 *4. GRINCH cherenkov detector*

234 The main purpose of the Ring Imaging Cherenkov is to provide additional particle iden-  
235 tification for offline pion rejection. The GRINCH consists of a tank with a maximum depth  
236 of 88.9 cm, with 4 cylindrical mirrors focussing the cherenkov light directly onto a 510 PMT

<sup>237</sup> array (60 lines of PMTs, with lines of 9 PMTs alternating with lines of 8 PMTs) placed away  
<sup>238</sup> from the beam. The radiation gas will be  $C_4F_8$ , which is by far the best compromise between  
<sup>239</sup> light yield for electrons and operating cost. With  $n - 1 = 1.35 \times 10^{-3}$ , the  $\pi$  threshold is only  
<sup>240</sup> about 2.7 GeV, so the additional pion rejection will be most effective below this threshold.

<sup>241</sup> As for the timing hodoscope The PMTs pulses are processed by NINO front-end cards  
<sup>242</sup> which, when the PMT pulse crosses the NINO threshold, will produce a digital signal to  
<sup>243</sup> be readout by VETROC TDCs, which for each PMT hit will record a leading time and a  
<sup>244</sup> trailing time. The analog signal will not be recorded however, which means that for each  
<sup>245</sup> PMT hit, the information of the number of not directly available (although it can in theory  
<sup>246</sup> be deduced from the time over threshold).

<sup>247</sup> All of this implies that the electron selection relies on the number of GRINCH PMT  
<sup>248</sup> firing, instead of relying on the signal amplitude.

249

## B. Hadron Calorimeter (HCal)

250 The Hadron Calorimeter (HCal) has been designed specifically to measure the recoil  
 251 nucleon for the SBS experiments. Specifically for this experiment (and for  $G_M^n$ ), HCal  
 252 combined with the SBS (48D48) magnet provides identification of the recoil nucleon, as  
 253 well as additional kinematic constraint and possibly timing information on the measured  
 254 interaction. Nucleon identification is illustrated on Fig. 5. This figure shows the compared  
 255 proton and neutron position distribution in HCal at the same electron kinematics. The  
 256 proton distribution is being shifted upwards by about 1 m compared to the neutron.

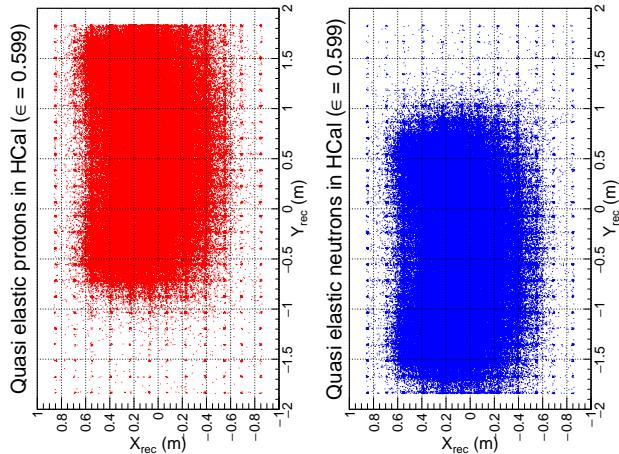

FIG. 5. Reconstructed HCal cluster from quasi-elastic events generated by G4SBS. The left distribution in red is for the proton, the right distribution in blue is for the neutron.

257

258

259 The HCal is composed of 288 modules arranged in an array of  $12 \times 24$  (Fig. ??) In front  
 260 of the full assembly is located a  $3/4$  in steel plate which purpose is double:  
 261

- 262 • initiate the hadronic shower to optimize the calorimeter response;
- 263 • shield the modules from a fraction of the low energy secondaries;

264 Each of these modules measures  $6 \times 6 \text{ in}^2$  section, for 3 ft length. They are composed of  
 265 alternating tiles of scintillators and iron around a central light guide which collects the light

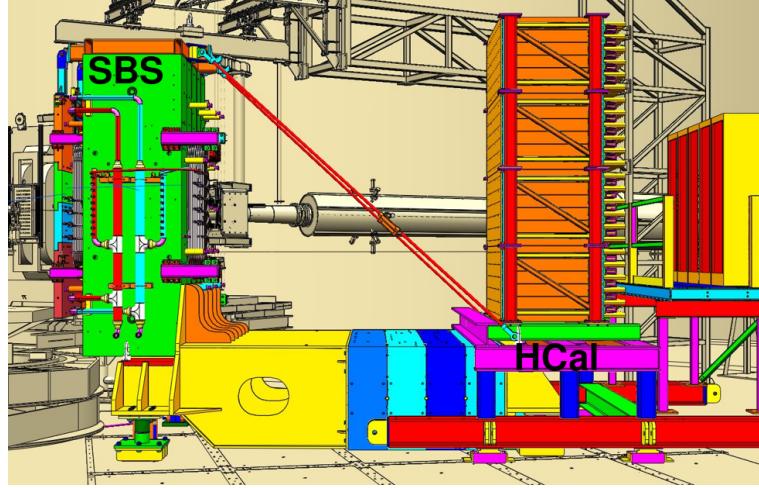

FIG. 6. CAD representation of HCal (right) with the SBS magnet (left)

<sup>266</sup> generated in the scintillators by the hadronic shower, and guides it to the PMT at the end of  
<sup>267</sup> the block. Cosmics tests have determined that the average light yield for the HCal modules  
<sup>268</sup> is around 5 photoelectrons per MeV deposited in the scintillator tiles.

<sup>269</sup> The PMTs are readout with FAD250 which sample the PMT signal every 40 ns and allow  
<sup>270</sup> to reconstruct the PMT pulse shape, hence its timing. They are also readout by TDCs which  
<sup>271</sup> provide additional timing information. Thanks to this, the timing resolution can be better  
<sup>272</sup> than 1 ns, which cosmics tests (in progress) seem to confirm.

<sup>273</sup> The energy resolution is intrinsically broad (see Fig. 9 in Section V), due mostly to the  
<sup>274</sup> small fraction of energy from the hadronic shower actually measured by the scintillator tiles  
<sup>275</sup> ( $\leq 0.1$  - refer yet again to Fig. 9).

276       **V. SIMULATIONS, ESTIMATIONS OF COUNTING RATES AND**  
 277       **ACCIDENTALS**

278       The estimations of counting rates accidentals have been performed using G4SBS, the  
 279       GEANT4-based simulation package developed for the SBS experiment [? ]. This package  
 280       includes a wide range of event generators, which allows to evaluate the rates for both events  
 281       of interest (signal) and background. The representation of the experiment apparatus in  
 282       G4SBS is shown in the high  $\epsilon$  configuration on Fig. 7.

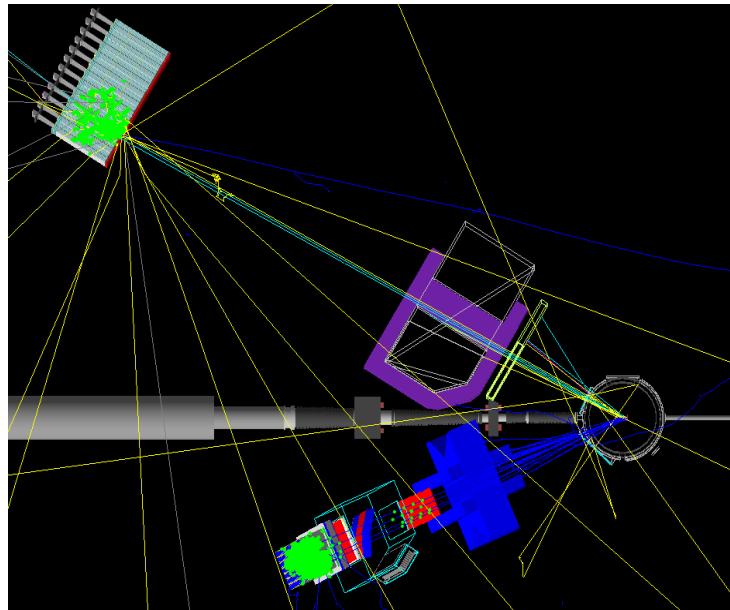

FIG. 7. Top view of the experimental apparatus model in G4SBS, shown in the high  $\epsilon$  configuration. The beam direction is indicated, as well as the main elements (HCal, SBS magnet, BigBite spectrometer)

283  
 284

285       **A. Background and trigger rates**

286       The main processes expected to contribute the trigger rates for the BigBite spectrometer  
 287       are:

288 • the inelastic electron nucleon scattering process;

289 • photons from inclusive  $\pi^0$  production;

290 • and to a lesser extent, charged pions.

291 One the other hand, we expect all sorts of hadronic backgrounds to contribute to the rates in  
 292 HCal, the dominant ones being pions. Both the inelastic scattering and the inclusive neutral  
 293 and charged pion production are implemented in G4SBS, the latter relying on the Wiser  
 294 parametrization [? ]. We may also considered the minimum-bias “beam-on-target” gener-  
 295 ator for the HCal background, especially at lower angle (all electromagnetic and hadronic  
 296 processes being built-in in G4SBS).

297 The thresholds to apply to each arm are determined as a function of the elastic peak. For  
 298 the electron arm, the threshold has been set at  $\mu_E - 2.5\sigma_E$ ,  $\mu_E$  and  $\sigma_E$  being respectively  
 299 the position and width of the fitted elastic peak. Fig. 8 presents the distributions of rate of  
 300 energy deposit for the different processes involved in the BigBite trigger rates.

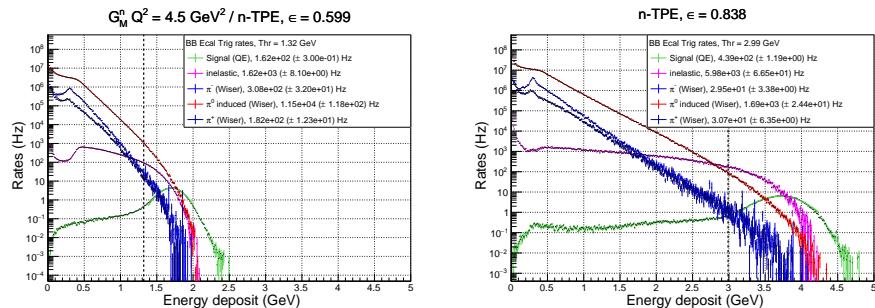

FIG. 8. Rates of the different process contributing to the BigBite electron arm trigger, for the low  $\epsilon$  (left) and the high  $\epsilon$  (right). Quasi-elastic is in green, inelastic in magenta,  $\pi^0$  in red,  $\pi^-$  in blue, and  $\pi^+$  in dark blue. Note the resolution for the elastic peak in the BigBite shower is  $\sim 0.3$  GeV.

301

302

303 Since HCal is a sampling calorimeter (meaning that only a fraction of the shower energy  
 304 is measured), it's resolution is significantly wider ( $\sim 0.7$  GeV). Due to this, the threshold  
 305 is at 90% efficiency (which corresponds to  $\sim 0.1$  GeV for both kinematics. Fig. 9 presents

306 the distributions of rate of energy deposit for the different processes involved in the BigBite  
 307 trigger rates.

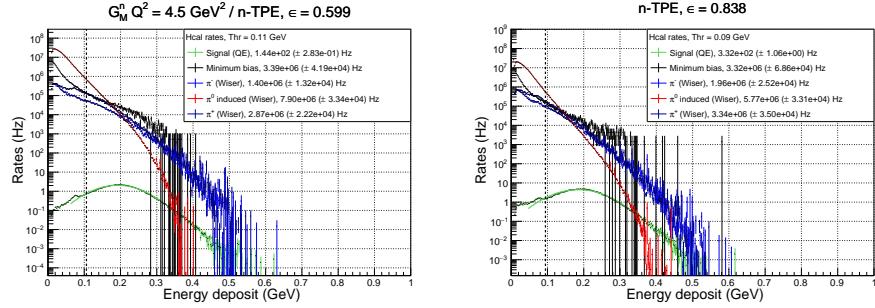

FIG. 9. Rates of the different process contributing to the HCal trigger, for the low  $\epsilon$  (left) and the high  $\epsilon$  (right). Quasi-elastic is in green, minimum bias in black,  $\pi^0$  in red,  $\pi^-$  in blue, and  $\pi^+$  in dark blue. Note the peak itself is around 0.2 GeV for 3.2 GeV nucleons.

308

309

310 The thresholds and trigger rates for each arm, as well as the coincidence rate (assuming  
 311 30ns coincidence window), are summarized in Table. I.

312

313 Note that for HCal, the “total rates” is either the sum of inclusive charged and neutral pions  
 314 evaluated with the Wiser cross sections *or* the “minimum bias” beam on target. We have  
 315 good reasons to think that the Wiser code results actually overestimate the HCal rates, but  
 316 for the sake of thoroughness, we have checked the coincidence rates assuming the sum of the  
 317 inclusive pions (evaluated with the Wiser cross sections) as the HCal rates.

318 In the worst case scenario, the coincidence rates could be as high as 5kHz, which might be  
 319 at the limit of manageability for the DAQ. However, a slight increase on the HCal threshold  
 320 (which would drop the efficiency from ∼90% to ∼85%) would decrease the total HCal rates by  
 321 ∼35% to 40% in this worst case scenario, which would make the situation more manageable  
 322 (3.3 kHz).

Point ( $\epsilon$ )	1 (0.599)		2 (0.838)	
	BigBite rates (Hz)	HCal rates (Hz)	BigBite rates (Hz)	HCal rates (Hz)
threshold (GeV)	1.32	0.106	2.99	0.090
Quasi-elastic	$1.62 \times 10^2$	$1.44 \times 10^2$	$4.39 \times 10^2$	$3.48 \times 10^2$
Inelastic	$1.62 \times 10^3$	-	$5.98 \times 10^3$	-
$\pi^-$ (Wiser)	$3.08 \times 10^2$	$1.40 \times 10^6$	$2.95 \times 10^2$	$1.96 \times 10^6$
$\pi^0$ (Wiser)	$1.15 \times 10^4$	$7.90 \times 10^6$	$1.69 \times 10^3$	$5.77 \times 10^6$
$\pi^+$ (Wiser)	$1.82 \times 10^2$	$2.87 \times 10^6$	$3.07 \times 10^2$	$3.34 \times 10^6$
Minimum bias	-	$3.39 \times 10^6$	-	$3.32 \times 10^6$ (*)
<i>Total</i>	$1.37 \times 10^4$	$1.22 \times 10^7$	$8.17 \times 10^3$	$1.11 \times 10^7$
(min. bias - HCal only)		/ $3.39 \times 10^6$		/ $3.32 \times 10^6$
<b>Coincidence rate</b>	$5.01 \times 10^3$		$2.72 \times 10^3$	
(with min. bias HCal)	$1.39 \times 10^3$		$8.14 \times 10^2$	

TABLE I. Trigger rates for BigBite and HCal, with the different process contributions separated, and the sum. For HCal, the total rates is either the sum of the (Wiser) inclusive pions or the minimum bias. The coincidence rates assume a 30 ns coincidence window.

323

### B. Accidentals: contamination from inelastic

324

The main source of contamination for the quasi-elastic comes from the inelastic electron-nucleon scattering. Most of this contamination can be cleaned out thanks to a selection on the center of mass energy

$$W^2 = M_N^2 + 2M_N^2(E - E') - Q^2, \quad (7)$$

327 and the missing transverse momentum of the nucleon

$$p_{\perp miss} = \sqrt{(q_x - p'_x)^2 + (q_y - p'_y)^2}, \quad (8)$$

328 where  $M_N$  is the mass of the nucleon,  $E$  and  $E'$  the initial and final energy of the electron,  
329 and  $q_{x,y}$ ,  $p'_{x,y}$  are the projections on  $x$ ,  $y$  of the vectors of the virtual photon and final nucleon.

<sup>330</sup> The distributions of these quantities (weighted with cross section and including detector res-  
<sup>331</sup> olutions) are displayed for quasi-elastic and inelastic scattering, and for proton and nucleon,  
<sup>332</sup> on Fig. 10 for the low  $\epsilon$  kinematic, and on Fig. 11 for the high  $\epsilon$  kinematic. Provided that

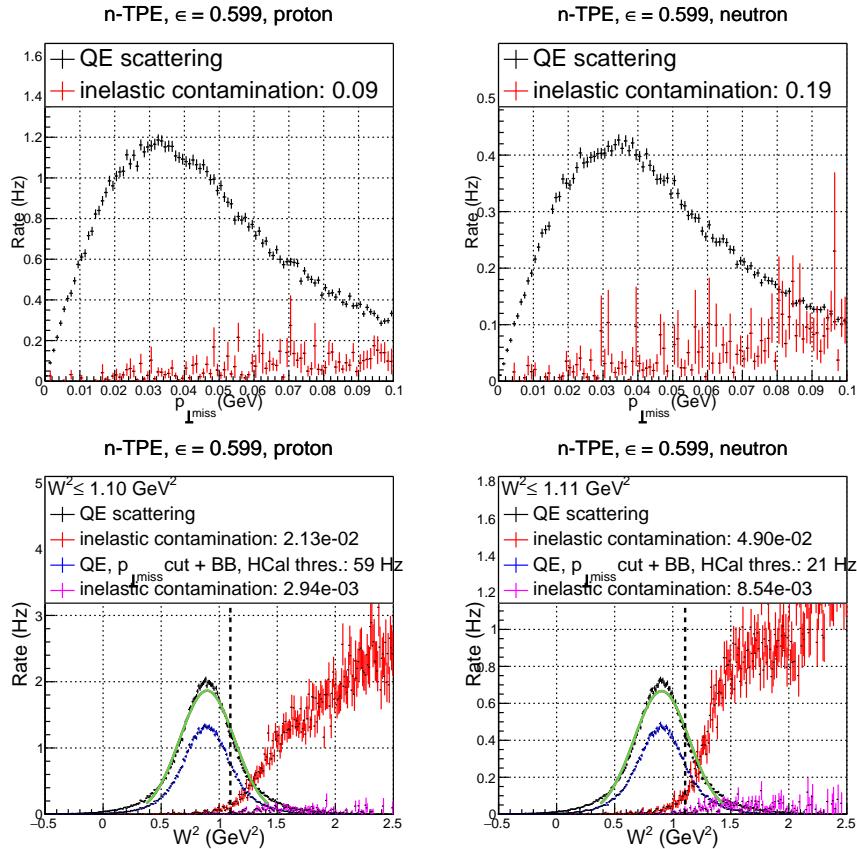

FIG. 10. Compared quasi-elastic and inelastic distributions (including detectors resolutions) for  $p_{\perp miss}$  (top) and  $W^2$  (bottom), for the low  $\epsilon$  kinematic. Comparison for protons is on the left, and comparison for neutrons is on the right. On the bottom panel, black and red are before the  $p_{\perp miss} \leq 0.1$  GeV selection, while blue and magenta are after  $p_{\perp miss} \leq 0.1$  GeV selection and application of BigBite shower and HCal thresholds.

<sup>333</sup>

<sup>335</sup>

<sup>336</sup> we are not limited by statistics and the sample purity is capital for our experiment, we set  
<sup>337</sup> the selection criteria on  $W^2$  and  $p_{\perp miss}$  to maximize inelastic contamination (ideally below  
<sup>338</sup> 1 %). Setting  $p_{\perp miss} \leq 0.1$  GeV and  $W^2 \leq 1.1$   $\text{GeV}^2$ , the inelastic contamination of the

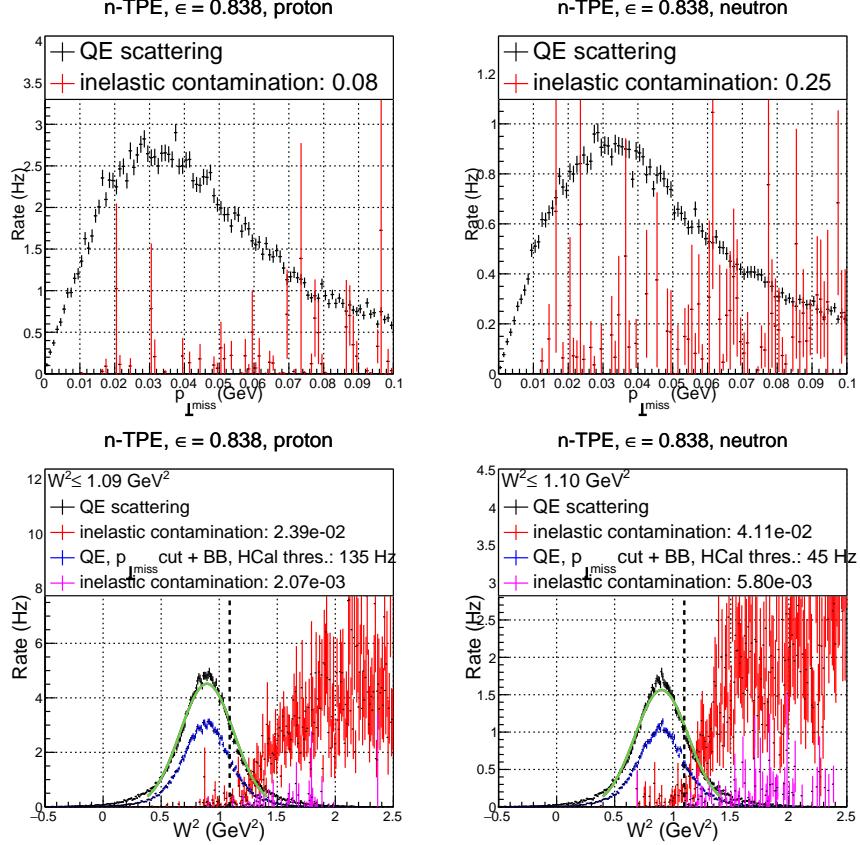

FIG. 11. Compared quasi-elastic and inelastic distributions (including detectors resolutions) for  $p_{\perp \text{miss}}$  (top) and  $W^2$  (bottom), for the high  $\epsilon$  kinematic. Comparison for protons is on the left, and comparison for neutrons is on the right. On the bottom panel, black and red are before the  $p_{\perp \text{miss}} \leq 0.1 \text{ GeV}$  selection, while blue and magenta are after  $p_{\perp \text{miss}} \leq 0.1 \text{ GeV}$  selection and application of BigBite shower and HCal thresholds.

<sup>339</sup> elastic sample ranges from 0.2 % to 0.9 %, while retaining  $\geq 60$  %.

340

### C. Quasi-elastic counting rates

<sup>341</sup> The signals for this experiment have been generated using the G4SBS elastic/quasi-elastic  
<sup>342</sup> generator. We generated 1M events sample for each kinematics, on a solid angle that was  
<sup>343</sup> larger than the detector acceptance. To evaluate the detector solid angle, we define simple

<sup>344</sup> criteria that each event has to pass, defined as the following;

- <sup>345</sup> • require a primary track, going through all 5 GEM layers (electron arm);
- <sup>346</sup> • require non-zero energy deposit in both the preshower and shower (electron arm);
- <sup>347</sup> • require non-zero energy deposit in HCal (hadron arm).

<sup>348</sup> The detector solid angle, for both proton and neutron, are defined in Table. II

Point ( $\epsilon$ )	$\Delta\Omega_e$ (msr)	$\Delta\Omega_e \otimes \Delta\Omega_n$ (msr)	$\Delta\Omega_e \otimes \Delta\Omega_p$ (msr)
1 (0.599)	52.4	46.7	47.2
2 (0.838)	32.7	20.8	22.2

TABLE II. Kinematics electron solid angle, and convoluted electron/hadron solid angle

<sup>349</sup>

<sup>350</sup> Then, we evaluate the detection efficiency. For the electron, we require the energy recon-  
<sup>351</sup> structed in the BigBite calorimeter to be above a threshold defined as  $thr = \mu_E - 2.5 * \sigma_E$ ,  
<sup>352</sup> as well as a minimum number of GRINCH PMTs fired due to the primary electron; For  
<sup>353</sup> HCal, we require the threshold to be such as we obtain 90% efficiency. These values are  
<sup>354</sup> summarized in Table. III.

Point ( $\epsilon$ )	BB thr. (GeV)	HCal thr. (GeV)	$\eta_{det\ e}$	$\eta_{det\ n}$	$\eta_{det\ p}$	$\eta_{sel\ n}$	$\eta_{sel\ p}$
1 (0.599)	1.32	0.11	0.902	0.904	0.892	0.589	0.605
2 (0.838)	2.99	0.09	0.808	0.889	0.882	0.617	0.647

TABLE III. Kinematics electron thresholds, particle detection efficiencies ( $\eta_{det}$ ), and efficiency of quasi-elastic selection  $\eta_{sel}$  separated for the proton and the neutron.

<sup>355</sup>

356 The counting rates are evaluated using the events that have passed the selection described  
357 above, and weighting those events with the cross section calculated by G4SBS, multiplied  
358 by the generation solid angle, using the formula:

$$N_{est} = \mathcal{L} \Delta t \times \sum_{i \in accepted \text{ evts}} \frac{d\sigma}{d\Omega} * \Delta\Omega_{Gen}/N_{Gen} \quad (9)$$

359 Events are “accepted” if they meet the following criteria:

- 360 • the electron is in the BigBite acceptance;
- 361 • the electron passes the BigBite threshold defined in Table III and gives signal in the  
362 GRINCH;
- 363 • the nucleon is in the HCal acceptance and passes the HCal threshold defined in Ta-  
364 ble III;
- 365 • the event passes the quasi-elastic selection defined in the previous section *i.e.*  $W^2 \leq 1.1 \text{ GeV}^2$   
366 and  $p_{\perp miss} \leq 0.10 \text{ GeV}$ .

367 The total quasi-elastic statistics  $N_{QE}$ , as well as the total form factor:  $F^2$

$$F^2 = \frac{N_{QE}}{\mathcal{L}_{exp} \cdot \Delta t \cdot d\sigma_{Mott}/d\Omega \cdot \Delta\Omega \cdot \eta} \quad (10)$$

368 and its statistical error  $\Delta F^2 = F^2/\sqrt{N_{QE}}$  are compiled for both kinematics in Table. ??,  
369 assuming a running time  $\Delta t = 12$  hours of running at a beam intensity of  $I_{exp} = 30 \mu\text{A}$  on  
370 a liquid deuterium target with length  $l_{tgt} = 15 \text{ cm}$  and density  $d_{tgt} = 0.169 \text{ g.cm}^{-3}$ .

371

372 The expression of the total form factor  $F^2$  is: where  $\Delta t$  the running time,  $\Delta\Omega$  is the  
373 convoluted BigBite-HCal solid angle,  $\eta$  is the product of all efficiencies (detection efficiencies  
374  $\eta_{det} \times$  selection efficiency  $\eta_{sel}$ ) , and  $\mathcal{L}_{exp}$  is the experimental luminosity:

$$\mathcal{L}_{exp} = \frac{I_{exp}}{q_e} * L_{tgt} * d_{tgt} \frac{\mathcal{N}_A}{m_D}. \quad (11)$$

Point ( $\epsilon$ )	$N_{QE}$ (e-n)	$N_{QE}$ (e-p)	$F_n^2$ ( $\times 10^{-3}$ )	$\Delta F_n^2$ ( $\times 10^{-6}$ )	$F_p^2$ ( $\times 10^{-3}$ )	$\Delta F_p^2$ ( $\times 10^{-6}$ )
1 (0.599)	$9.07 \times 10^5$	$2.55 \times 10^6$	0.99	1.04	2.73	1.70
2 (0.838)	$1.94 \times 10^6$	$5.83 \times 10^6$	0.72	0.52	1.93	0.80

TABLE IV. Quasi-elastic counting rates, and “reduced cross section” as defined by Eq. 10. These rates assume  $\Delta t = 12$  hours of running at a beam intensity of  $I_{exp} = 30 \mu\text{A}$  on a liquid deuterium target with length  $l_{tgt} = 15 \text{ cm}$  and density  $d_{tgt} = 0.169 \text{ g.cm}^{-3}$

<sup>375</sup> The calculation of the  $F_2$  term requires the evaluation of the Mott cross section

$$\frac{d\sigma_{Mott}}{d\Omega} = (\hbar c \alpha_{EM})^2 \left( \frac{e}{2E} \right)^2 \left( \frac{\cos\theta_e/2}{\sin^2\theta_e/2} \right)^2 \frac{E'}{E} \quad (12)$$

<sup>376</sup> The Mott cross section has been calculated with the weighted average of the electron variables  
<sup>377</sup> (momentum and polar angle).

Point ( $\epsilon$ )	$\langle \theta_e \rangle$ (deg)	$\langle k' \rangle$ (GeV)	$\langle Q^2 \rangle$ (GeV $^2$ )	$\sigma_{Mott}$ (nb sr $^{-1}$ )
1 (0.599)	41.7	2.01	4.47	6.62
2 (0.838)	22.9	4.26	4.40	48.0

TABLE V. Cross-section weighted average of kinematic variables over the BigBite acceptance. The Mott cross section has been evaluated at these values.

<sup>378</sup>

379

## VI. PROPOSED MEASUREMENTS

380 We propose to use the same experimental setup of E12-09-019 experiment. We will add  
 381 a kinematic point at  $Q^2 = 4.5 \text{ (GeV/c)}^2$ , but with a higher  $\epsilon$  value. This additional point  
 382 along with the data point of E12-09-019 experiment will allow us to perform LT separation  
 383 and obtain (in one-photon approximation) the  $G_E^n$  value. Table 1 displays the kinematic  
 384 setting of the proposed experiment.

Point	$Q^2$ (GeV/c) <sup>2</sup>	E (GeV)	E' (GeV)	$\theta_{BB}$ degrees	$\theta_{SBS}$ degrees	$\epsilon$ (%)	$\Delta\sigma$ (%)	$\Delta TPE$ (%)
1	4.5	4.4	2.0	41.88	24.67	0.599		
2	4.5	6.6	4.2	23.23	31.2	0.838		

TABLE VI. Kinematic settings of the proposed experiment. The blue row is a kinematic point of E12-09-019 experiment.

385

386

## VII. BEAM TIME REQUEST

387     **We request 48 hours total time (32 hours of beam-on target)** to measure the  
 388     two-photon effect (and  $G_E^n$  in one-photon approximation) at  $Q^2 = 4.5$  ( $\text{GeV}/c$ ) $^2$  through a  
 389     measurement of the cross sections of the reaction  $D(e,e'N)$  at a large value of the virtual  
 390     photon polarization  $\epsilon=0.84$ . *The measurement at  $Q^2 = 4.5$  ( $\text{GeV}/c$ ) $^2$ ,  $\epsilon=0.60$  is already*  
 391     *scheduled as part of the SBS  $G_M^n$  experiment E12-09-019.*

392     We plan to take 12 hours of data at a full luminosity of  $2.86 \times 10^{38} \text{ cm}^{-2}\text{s}^{-1}$ , which  
 393     corresponds to a beam intensity of  $I_{exp} = 30 \mu\text{A}$  on a liquid deuterium target with length  
 394      $l_{tgt} = 15 \text{ cm}$  and density  $d_{tgt} = 0.169 \text{ g.cm}^{-3}$ . To have a better handle on our backgrounds,  
 395     we also plan to take 12 hours of data at half luminosity (basically by lowering the beam  
 396     intensity by a factor 2). In each of these configurations, we also need to take data on a  
 397     “dummy” target (*i.e.* on a target cell identical to the one used for production, but empty)  
 398     to understand the contamination of our data from the target walls.

399     In addition to this beam time, we also require 16 hours (two shifts) to change the exper-  
 400     imental configuration. This configuration change means:

- 401       • SBS magnet and the hadronic calorimeter (HCal) angle change;
- 402       • BigBite spectrometer angle and distance change;
- 403       • Beam energy change;

404     These tasks may be done in parallel, but the SBS configuration is the most-time consuming  
 405     task, and determines the time required to perfomr this configuration change.

406     The projected use of this time is summarized in Table. ??.

407

408     This experiment will take place in Hall A, along the already scheduled SBS  $G_M^n$  experiment  
 409     E12-09-019, utilizing the BigBite spectrometer to detect electrons scattered off the liquid  
 410     deuterium target, and HCal calorimeter to detect the recoiling neutron and proton.

Task	Target	$I_{exp}$	time requested
Data taking (Prod.)	15 cm LD <sub>2</sub>	30 $\mu$ A	12 hours
Data taking (Syst.)	15 cm “Dummy”	30 $\mu$ A	4 hours
Data taking (Prod.)	15 cm LD <sub>2</sub>	15 $\mu$ A	12 hours
Data taking (Syst.)	15 cm “Dummy”	15 $\mu$ A	4 hours
Setting changes (SBS, BigBite angles, beam energy) 16 hours			
<b>Total</b>			<b>48 hours</b>

TABLE VII. Summary table for the beam time request. Setting changes include SBS and Bigte bite angles change, as well as a beam energy change.

411 Data taking (if approved by PAC48) will take place in summer 2021 during the approved  
 412 and scheduled run of the GMn, E12-09-019, experiment, which is going to measure the  $e - n$   
 413 elastic scattering cross section at  $Q^2 = 4.5$  (GeV/c)<sup>2</sup> at  $\epsilon=0.60$ .

414 The set of instrumentation and required beam current for proposed measurement is iden-  
 415 tical to one in the GMn experiment. The beam energy of 6.6 GeV will be used. One of two  
 416 data points required for the cross section LT separation is already in the data taking plan of  
 417 GMn.

418 There are no other measurements of TPE in the  $e - n$  elastic scattering and knowledge  
 419 of the TPE is essential for the understanding of the elastic electron scattering from neutron  
 420 (and proton) and hadron structure. Furthermore, it is a necessary input in the analysis and  
 421 interpretation of a wide range of electron scattering processes.

422 The kinematics of our measurements emphasize the same  $Q^2$  range where TPE in  $e - p$   
 423 elastic scattering was observed to dominate in Rosenbluth slope. Measuring at this high  
 424 momentum transfers will provide unique input for testing TPE calculations [4].

425 We propose to measure the Rosenbluth slope and extract (in one-photon approximation)  
 426  $\delta G_E^n/G_M^n$  to an accuracy of 0.15, which would bring its precision to a level comparable with  
 427 that of the double polarization experiments GEN-RP and GEN-He3 at such value of  $Q^2$ .  
 428 Such precision should be sufficient to detect the TPE contribution to the  $e - n$  Rosenbluth  
 429 slope on the three sigma level.
